University of Cincinnati research scientists are warning former Fernald workers there may be a second, more significant source of radon they may have been exposed to at the now closed facility.

The new UC study says six silos filled with uranium ore in the production area may have resulted in high radon exposure to 12% of workers at the site.

Third shift workers may have been affected the most.

The Crosby Township site in northwest Hamilton County has been the scene of a a $4 billion clean-up since it closed in 1989.
